## Motion

Chang-Su Kim

## 2D Motion vs. Optical Flow

- True 2D motion
  - There is 3D motion between object and camera
  - It is projected onto 2D imaging plane

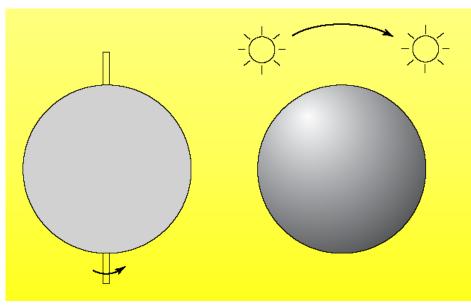

# 2D Motion vs. Optical Flow

### Optical flow

- observed, perceived, apparent 2D motion based on changes in pixel luminance
- It also depends on illumination and object surface texture
- It may not represent true 2D motion

On the left, a sphere is rotating under a constant ambient illumination, but the observed image does not change.

On the right, a point light source is rotating around a stationary sphere, causing the highlight point on the sphere to rotate.

# **Optical Flow Equation**

- Given only video sequence without any other information (such as illumination condition), we cannot estimate true 2D motion.
- The best one can hope to estimate is optical flow
- Constant intensity assumption → optical flow equation

Under "constant intensity assumption":

$$\psi(x+d_x,y+d_y,t+d_t) = \psi(x,y,t)$$

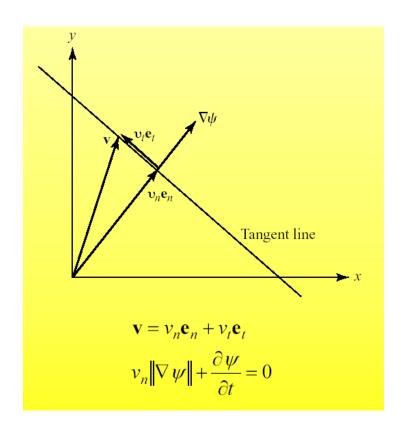

But, using Taylor's expansion:

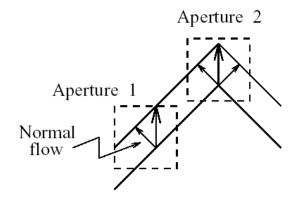

$$\psi(x+d_x,y+d_y,t+d_t) = \psi(x,y,t) + \frac{\partial \psi}{\partial t} + \frac{\partial \psi}{\partial t} + \frac{\partial \psi}{\partial t}$$
spatial optical flow

$$\frac{\partial \psi}{\partial x} d_x + \frac{\partial \psi}{\partial y} d_y + \frac{\partial \psi}{\partial t} d_t = 0 \quad \text{or} \quad \frac{\partial \psi}{\partial x} v_x + \frac{\partial \psi}{\partial y} v_y + \frac{\partial \psi}{\partial t} = 0 \quad \text{or} \quad \nabla \psi \cdot \mathbf{v} + \frac{\partial \psi}{\partial t} = 0$$

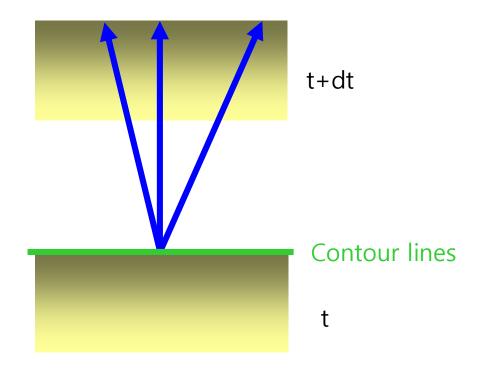

### Ambiguities in Optical Flow Estimation

- Optical flow equation constrains the motion vector in the gradient direction  $v_n$  only
- The flow vector in the tangent direction  $v_t$  is under-determined
  - We can only determine the displacement that is orthogonal to the edges
- In regions with constant brightness  $\nabla \psi = 0$ , the flow is indeterminate
  - Optical flow estimation is unreliable in regions with flat texture and more reliable near edges

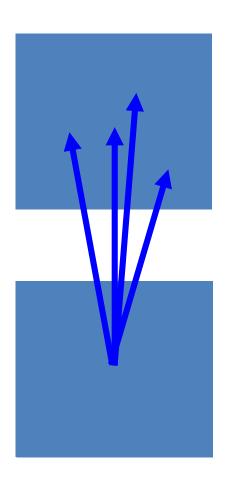

### Ambiguities in Optical Flow Estimation

### Ambiguities in Optical Flow Estimation

## Example

- Consider a video signal s(x, y, t) defined over the entire 3-D space (x, y, t), where s(x, y, t) is generated from one object, which undergoes translational motion with a uniform constant velocity  $(v_x, v_y)$ . Suppose that s(x, y, 0) = x + y + xy.
  - 1. Determine s(x, y, t).
  - 2. Show that in this case the following optical flow equation holds true.

$$v_x \frac{\partial s(x, y, t)}{\partial x} + v_y \frac{\partial s(x, y, t)}{\partial y} + \frac{\partial s(x, y, t)}{\partial t} = 0$$

#### General Considerations for Motion Estimation

### Two categories of approaches

- Feature based
  - · Correspondence between edges, points, etc
  - Object tracking, 3D reconstruction from 2D
- Intensity based
  - Optical flow estimation based on constant intensity assumption
  - Motion compensated prediction and filtering
  - Focus in this class

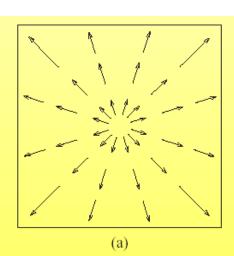

#### Three important questions

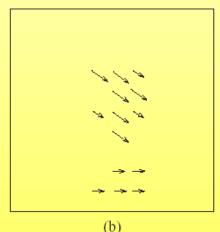

- How to represent the motion field?
- Which cost function (criterion) to use to estimate motion parameters?
- Which optimization technique?

## Motion Representation

#### Global:

Entire motion field is represented by a few global parameters

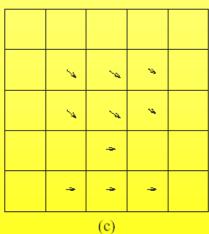

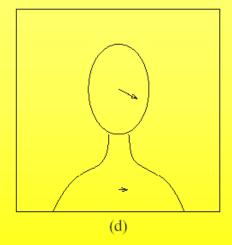

Pixel-based:
One MV at each pixel,
with some smoothness
constraint between
adjacent MVs.

#### Block-based:

Entire frame is divided into blocks, and motion in each block is characterized by a few parameters.

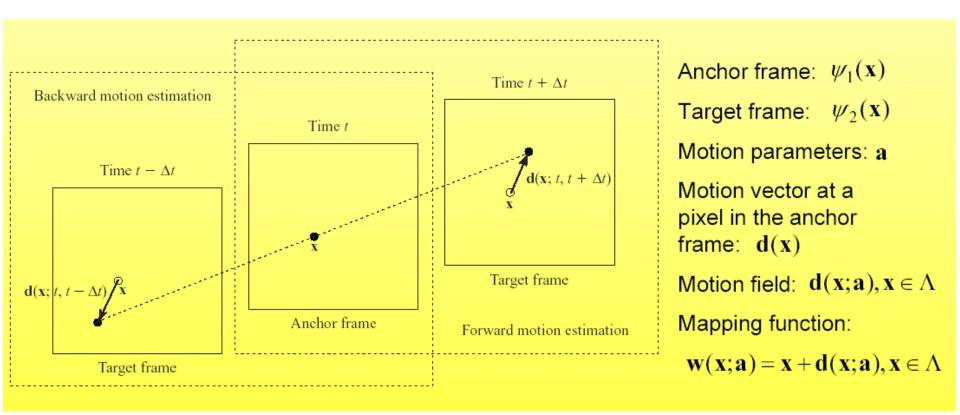

Region-based:
Entire frame is divided into regions, each region corresponding to an object or sub-object with consistent motion, represented by a few parameters.

Other representation: mesh-based (control grid) (to be discussed later)

## **Notations**

## **Motion Estimation Criteria**

Minimize displaced frame difference

$$E_{DFD}(\mathbf{a}) = \sum_{\mathbf{x} \in \Lambda} |\psi_2(\mathbf{w}(\mathbf{x}; \mathbf{a})) - \psi_1(\mathbf{x})|^p$$

For p = 2 (MSE), the necessary condition for minimum is that the derivative is zero. Let  $\mathbf{z} = \mathbf{w}(\mathbf{x}; \mathbf{a}) = \mathbf{x} + \mathbf{d}(\mathbf{x}; \mathbf{a})$ . Then, the derivative is given by

$$\frac{\partial E_{DFD}}{\partial \mathbf{a}} = 2 \sum_{\mathbf{x} \in \Lambda} (\psi_2(\mathbf{z}) - \psi_1(\mathbf{x})) \frac{\partial \psi_2}{\partial \mathbf{z}} \frac{\partial \mathbf{z}}{\partial \mathbf{a}}$$

$$= 2 \sum_{\mathbf{x} \in \Lambda} (\psi_2(\mathbf{z}) - \psi_1(\mathbf{x})) \frac{\partial \psi_2}{\partial \mathbf{z}} \frac{\partial \mathbf{d}}{\partial \mathbf{a}}$$

## Motion Estimation Criteria

Optical Flow Equation

$$\frac{\partial \psi}{\partial x} d_x + \frac{\partial \psi}{\partial y} d_y + \frac{\partial \psi}{\partial t} d_t = 0$$

$$\Rightarrow \frac{\partial \psi}{\partial x} v_x + \frac{\partial \psi}{\partial y} v_y + \frac{\partial \psi}{\partial t} = 0$$

where  $\mathbf{d}(\mathbf{x}; \mathbf{a}) = [d_x, d_y]^T$  and  $\mathbf{v}(\mathbf{x}; \mathbf{a}) = [v_x, v_y]^T = [d_x/d_t, d_y/d_t]^T$ .

Thus, obtain the motion vector parameters a which minimizes the cost function

$$E_{OF}(\mathbf{a}) = \sum_{\mathbf{x} \in \Lambda} |\frac{\partial \psi}{\partial \mathbf{x}} \mathbf{v}(\mathbf{x}; \mathbf{a}) + \frac{\partial \psi}{\partial t}|^p$$

## Lucas-Kanade Method

- Based on optical flow equation
- Assuming all pixels in a small block surrounding a pixel have the same motion vector

## Lucas-Kanade Method

- Optical Flow Equation  $\frac{\partial \psi}{\partial x}v_x + \frac{\partial \psi}{\partial y}v_y + \frac{\partial \psi}{\partial t} = 0$ 
  - For each pixel one equation two unknowns  $(v_x, v_y)$
  - Under-determined system
- Idea
  - Assume that a block  $\mathcal{B}$  centered around the current pixel has the same motion and then minimize

$$E(v_x, v_y) = \sum_{\mathbf{x} \in \mathcal{B}} \left( \frac{\partial \psi}{\partial x}(\mathbf{x}) v_x + \frac{\partial \psi}{\partial y}(\mathbf{x}) v_y + \frac{\partial \psi}{\partial t}(\mathbf{x}) \right)^2$$

Then, the optimal vector is set as the vector of the current pixel

## Lucas-Kanade Method

- Solution
  - By setting the partial derivatives with respect to  $v_x$  and  $v_y$  to zeros

$$\sum_{\mathbf{x} \in \mathcal{B}} \left( \frac{\partial \psi}{\partial x} (\mathbf{x}) v_x + \frac{\partial \psi}{\partial y} (\mathbf{x}) v_y + \frac{\partial \psi}{\partial t} (\mathbf{x}) \right) \frac{\partial \psi}{\partial x} (\mathbf{x}) = 0,$$

$$\sum_{\mathbf{x} \in \mathcal{B}} \left( \frac{\partial \psi}{\partial x}(\mathbf{x}) v_x + \frac{\partial \psi}{\partial y}(\mathbf{x}) v_y + \frac{\partial \psi}{\partial t}(\mathbf{x}) \right) \frac{\partial \psi}{\partial y}(\mathbf{x}) = 0,$$

we have

$$\begin{bmatrix} v_x \\ v_y \end{bmatrix} = -\begin{bmatrix} \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial x}(\mathbf{x}) \frac{\partial \psi}{\partial x}(\mathbf{x}) & \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial x}(\mathbf{x}) \frac{\partial \psi}{\partial y}(\mathbf{x}) \\ \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial x}(\mathbf{x}) \frac{\partial \psi}{\partial y}(\mathbf{x}) & \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial y}(\mathbf{x}) \frac{\partial \psi}{\partial y}(\mathbf{x}) \end{bmatrix}^{-1} \begin{bmatrix} \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial x}(\mathbf{x}) \frac{\partial \psi}{\partial t}(\mathbf{x}) \\ \sum_{\mathbf{x} \in \mathcal{B}} \frac{\partial \psi}{\partial y}(\mathbf{x}) \frac{\partial \psi}{\partial t}(\mathbf{x}) \end{bmatrix}$$
